Workflows

- Workflows are an abstraction of business processes.
- A workflow normally comprises a number of logical steps, which are known as tasks, dependencies between tasks, routing rules, and participants.
- A Workflow system reads, automates, processes, and manages workflows by coordinating the sharing and routing of information.

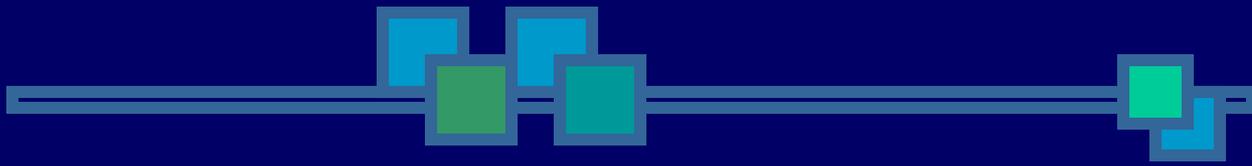

Workflow Example

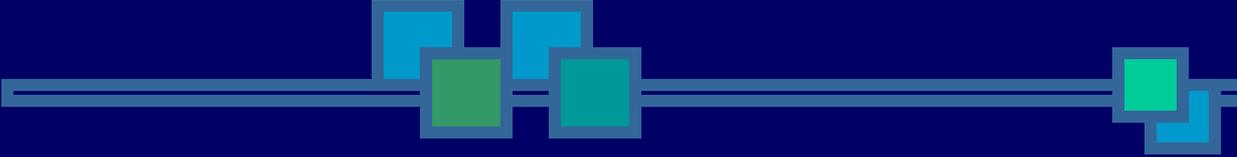

Web Services

- The importance of Web services has been recognize by the academia and by commercial organizations.
- Several efforts are being carried to develop a specification language for Web services.
- Approaches include XLANG [XLANG, 01], WSLF [WSLF, 01], and DAML-S [DAML-S, 01].

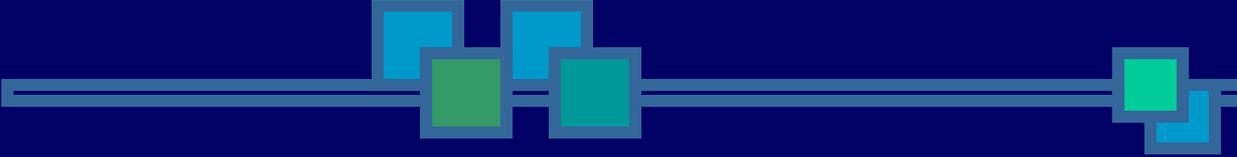

Web Services and Workflows

- Web service composition can be represented using workflows
- Of specific interest is cross-organizational workflow (workflows that span across organizations)

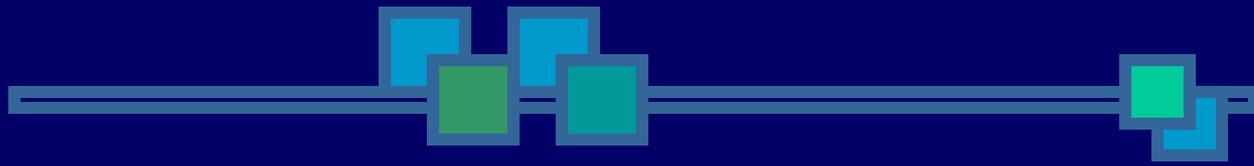

Problem Statement

- In e-commerce processes, suppliers and customers define a binding agreement or contract between the two parties, specifying quality of service (QoS) items such as products or services to be delivered, deadlines, quality of products, and cost of service. **Management of QoS directly impacts success of organizations participating in e-commerce.**

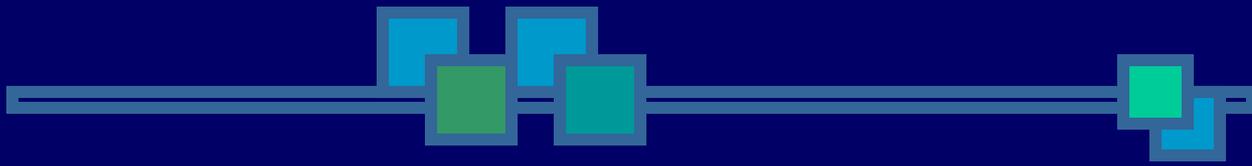

Quality of service

- Quality of service management is indispensable for organizations striving to achieve a higher degree of competitiveness.
- Processes executed under the control of an enactment system can be characterized and quantified according to various dimensions.
- We call the set of dimensions associated with quality of service workflow quality of service (QoS).
- The computation of QoS metrics allow organizations to better align their vision and operational processes.

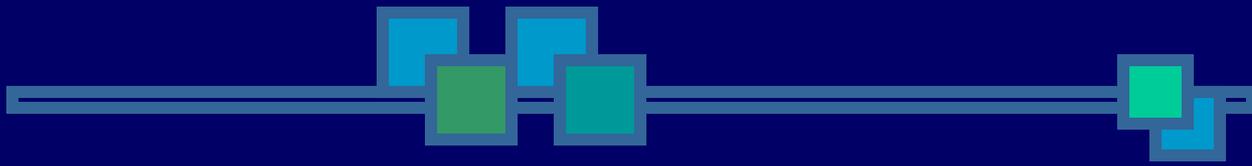

Research issues

- **Specification.** What dimensions need to be part of the Quality of Service for workflows?
- **Computation.** What methods and algorithms can be used to predict QoS?
- **Monitoring.** What kind of wQoS monitoring tools need to be developed?
- **Control.** What mechanisms need to be developed to control workflow processes, in response to unsatisfactory QoS metrics?

QoS Model Requirements

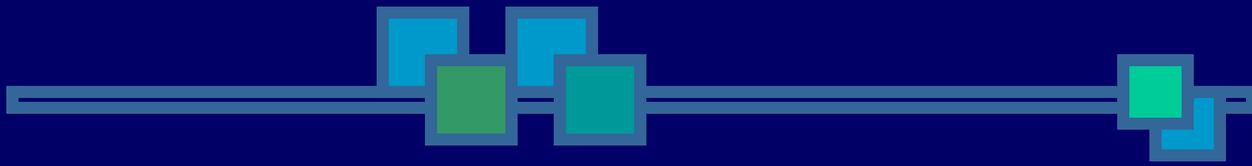

- The quality dimensions represented in the QoS model needs to be computable
- There must exist a QoS function at each node of the process tree that can be applied to its children.
- From this observation we developed a QoS model for which all its dimensions are computable.

QoS Model

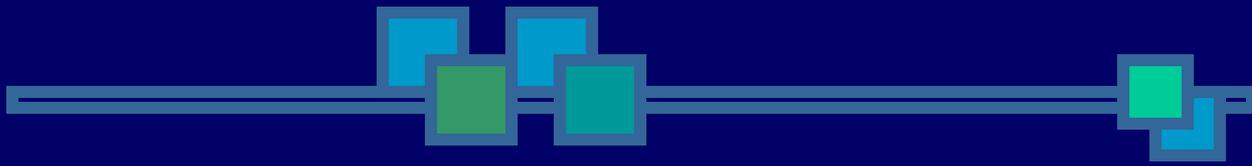

- QoS describes non-functional properties of a workflow. It is an important complement to the operational description of workflows.
- The QoS model is composed with four dimensions
 - Time
 - Time associated with the execution of a task or workflow.
 - Cost
 - Cost associated with the execution of a task or of a workflow.
 - Reliability
 - The probability of a task or workflow to succeed.
 - Fidelity
 - The accuracy of task's operations

QoS

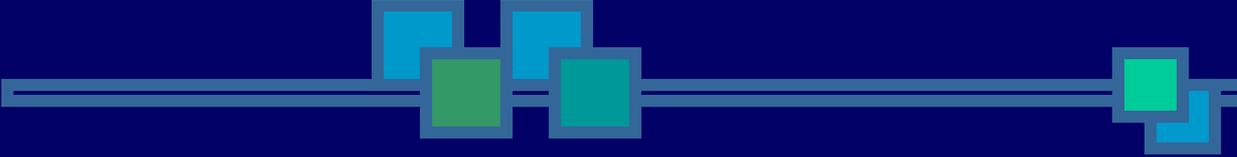

QoS - Time

- Time is a common and universal measure of performance.
- For workflow systems, it can be characterize defined as the total time needed by an instance to transform a set of inputs into outputs.
- The first measure of time is task cycle time (T_{CT}).
- The task cycle time can be breakdown in two major components: delay time and process time.
 - $T_{CT}(t) = T_{DT}(t) + T_{PT}(t)$

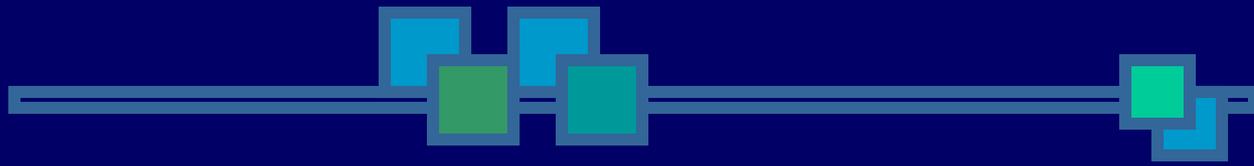

QoS - Cost

- Task cost represents the cost associated with the execution of workflow tasks.
- Cost is an important factor, since organizations need to operate according to their financial plan.
- Task cost (TC) can be broken down in into two major components: processing enactment cost and task realization cost.
 - $TC(t) = TEC(t) + TRC(t)$

QoS - Reliability

- Task Reliability (T_R) corresponds to the likelihood that the components will perform for its users when the user demands it and it is a function of failure rate.
- This dimension follows from one of the popular discrete-time stable reliability model proposed in [Nelson, 73].
 - $TR(t) = 1 - \text{failure rate}$

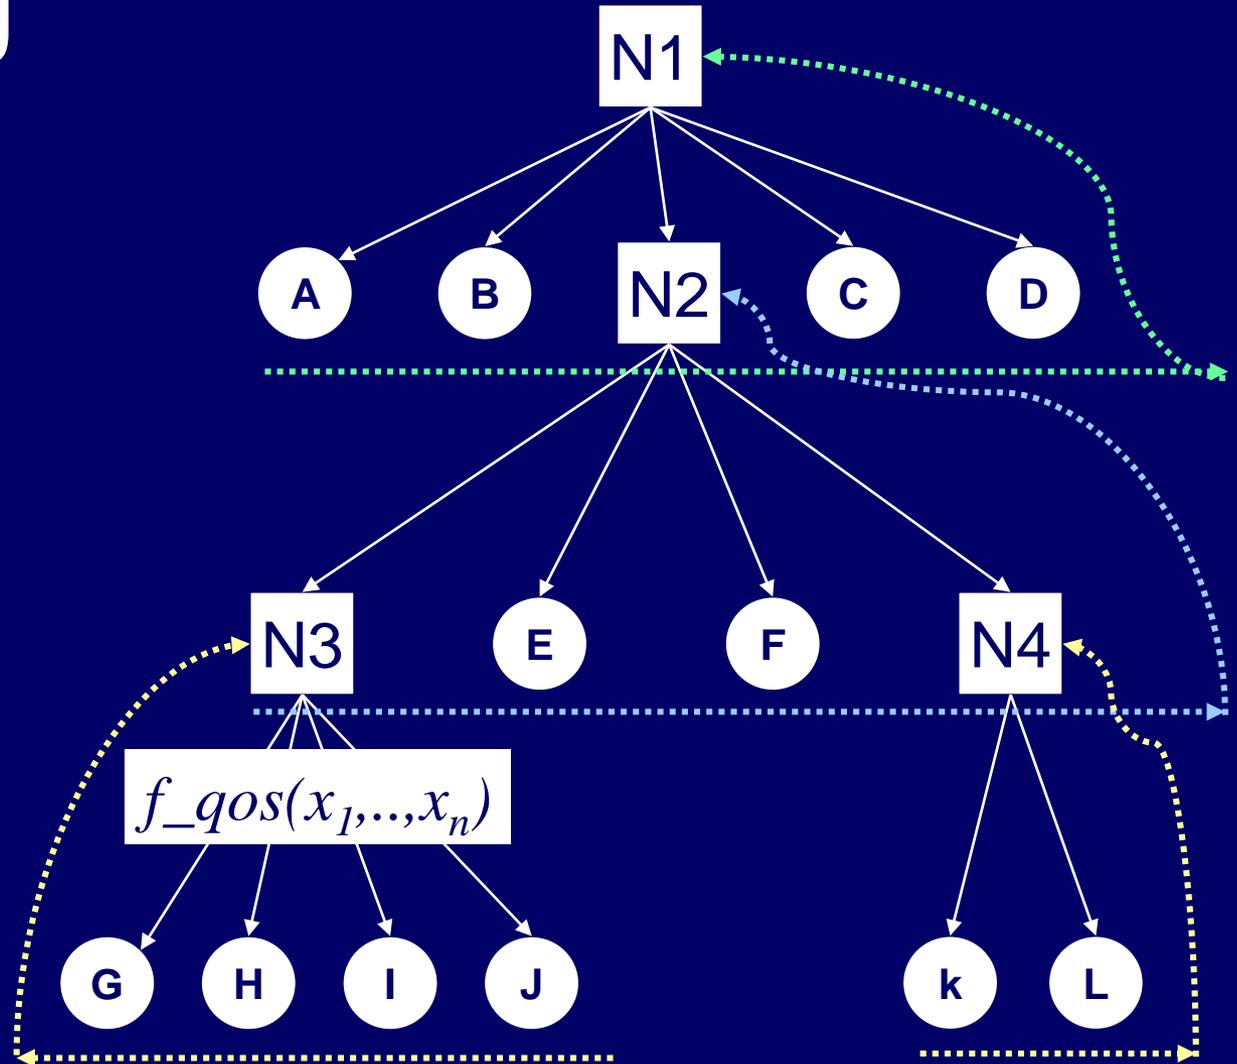

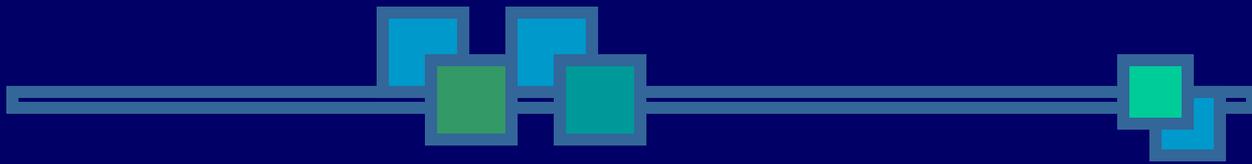

QoS - Fidelity

- Fidelity is a function of effective design and refer to an intrinsic property or characteristic of a good produced or service rendered.
- Workflow tasks have a fidelity (T_F) vector dimension composed by a set of fidelity attributes ($T_{F(t).ai}$), to reflect and quantify tasks operations.
- Depending on the task type different strategies are used to set fidelity attributes.

Computing QoS

Computer Aided Workflow Design based on
Semantics and QoS specifications.

Dynamic Workflow Adaptation.

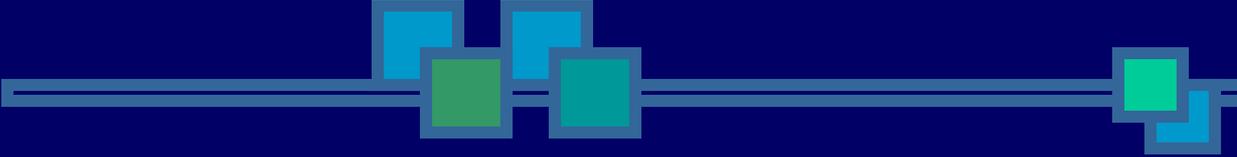

Computer-Aided Design based on Semantics

- Designing cross-organizational workflows is a complex process.
- Different components (tasks) from different organizations need to be coupled together.
- It is important for users to be aided during the design process.
- The system can help users, with the provision of task semantic fitness indicators.
- Design time validation

Research issues

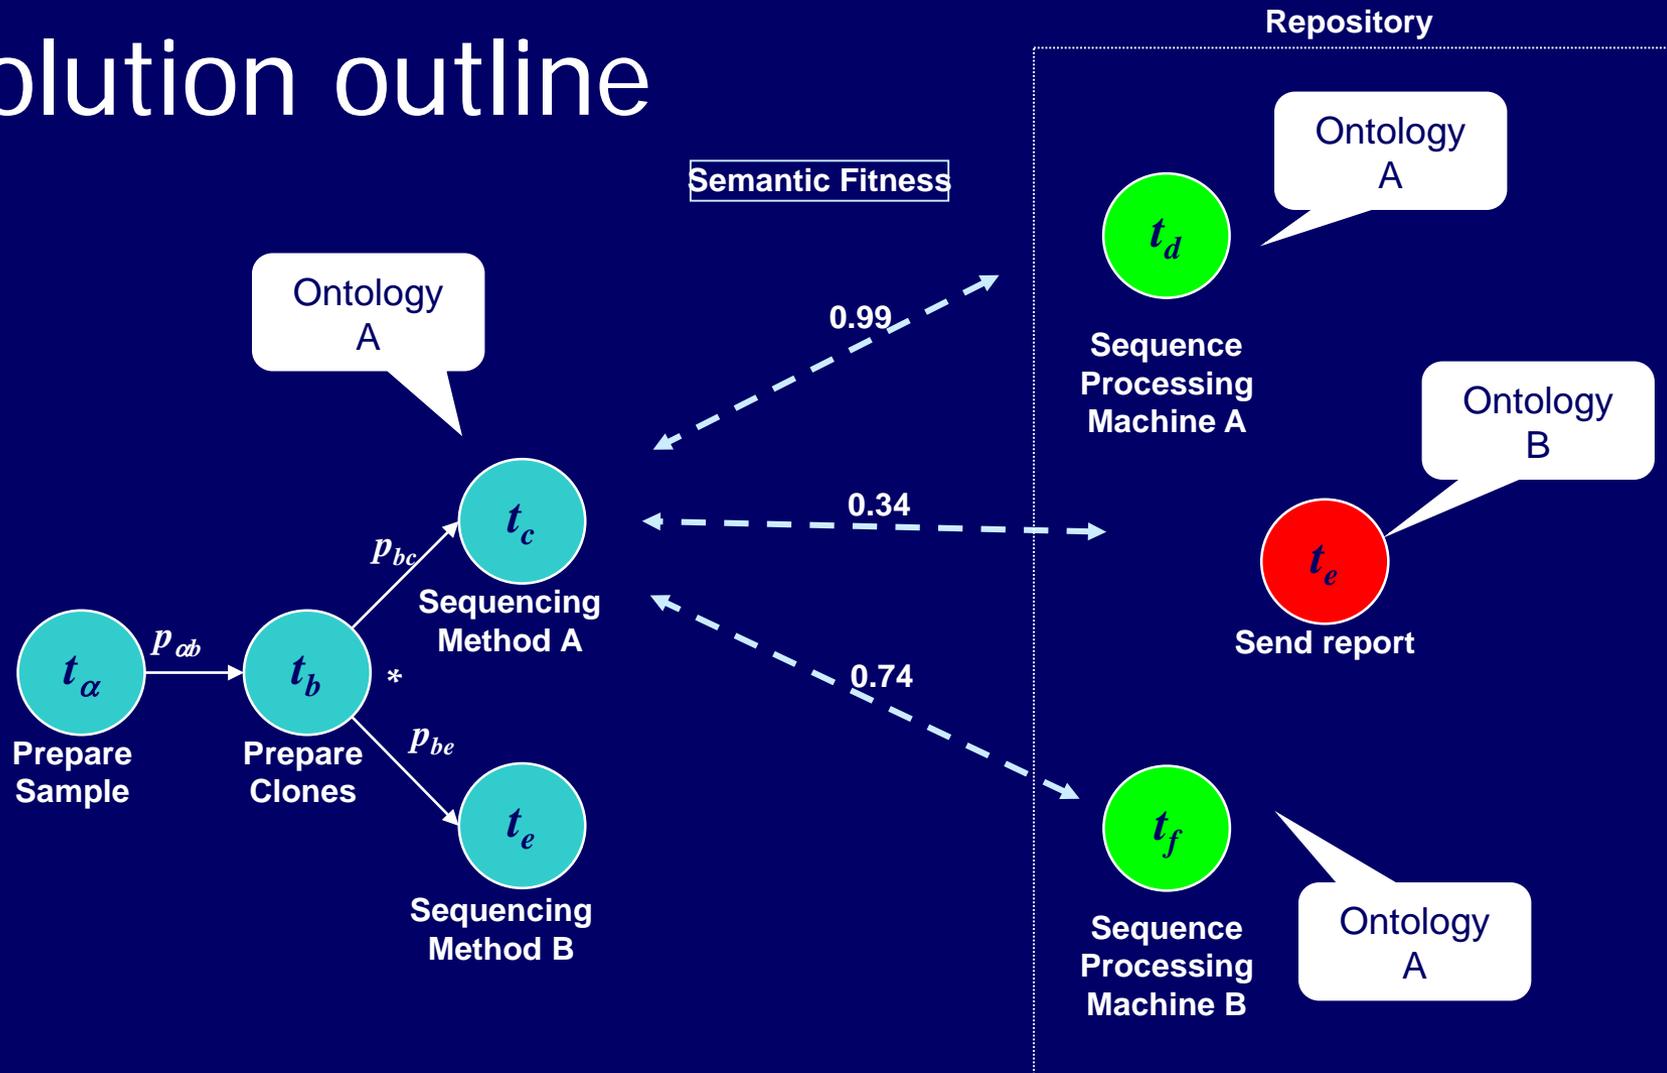

- **Specification.** How semantics can increase workflow tasks specification richness to facilitate and automate workflow process design.
- **Selection/Reuse.** How can tasks be searched, ranked and selected from repositories based on syntactic and semantic match.
- **Composition.** How semantics can facilitate the resolution of data and schematic conflicts among tasks.

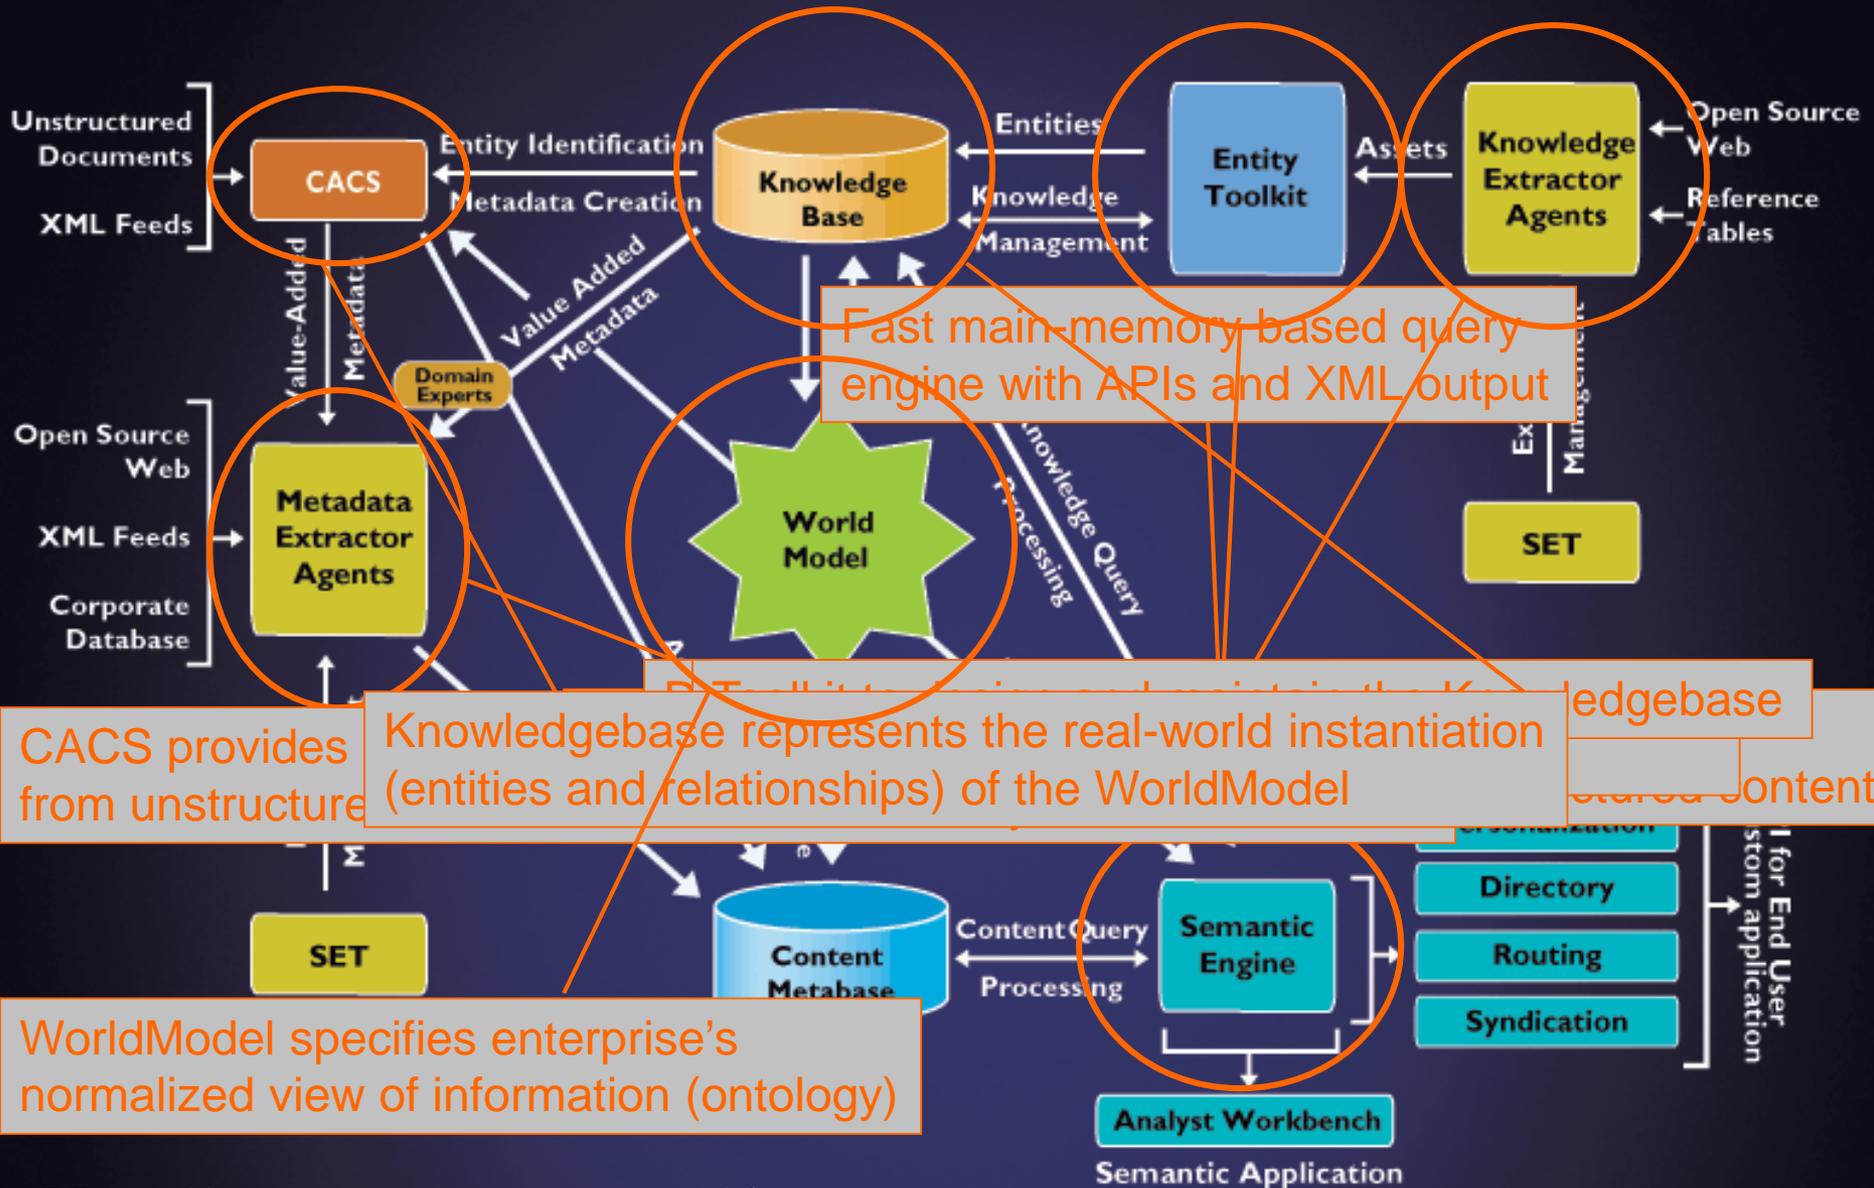

Solution Outline

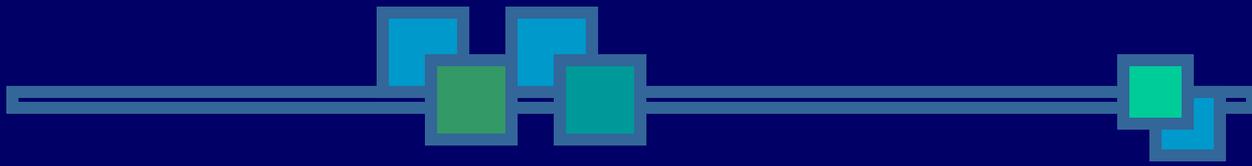

- **Specification.** Each workflow task is associated with ontologies, describing the task functionality, interface, and QoS.
- **Selection.** The tasks selected to design a workflow are ranked based on a semantic and syntactic fitness function.
- **Composition.** During workflow composition wQoS metrics are computed to allow the user to control workflow quality of service.

Solution outline

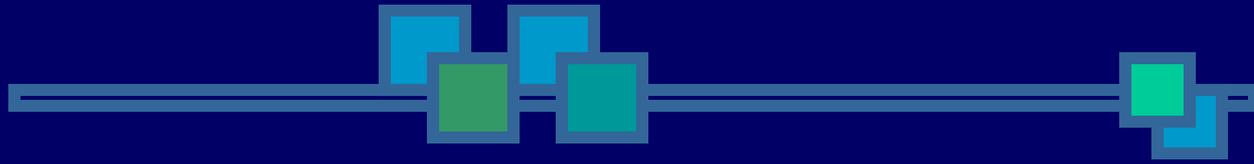

SCORE Semantic Technology System Architecture

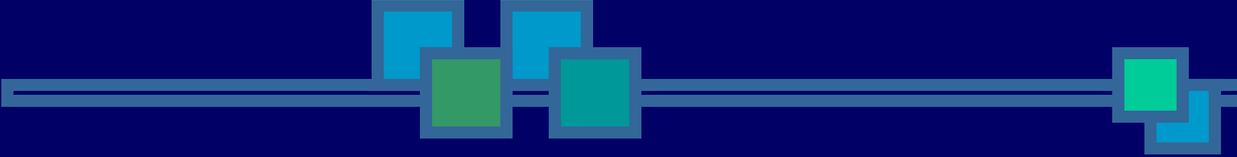

Workflow Adaptation

- In modern economies and organizations, business processes change has become a constant.
- There is a constant need for continuous workflow design improvement.

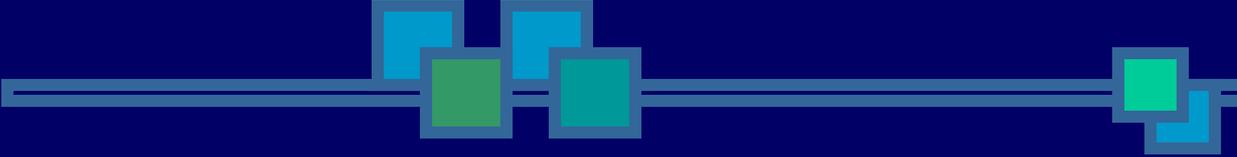

Research issues

- **Detection.** When should workflows be dynamically adapted?
- **Change Analysis.** When adaptation is required how can alternative be generated?
- **Change Introduction.** When can adaptation be made to currently running workflows without violating its consistency and other constraints?

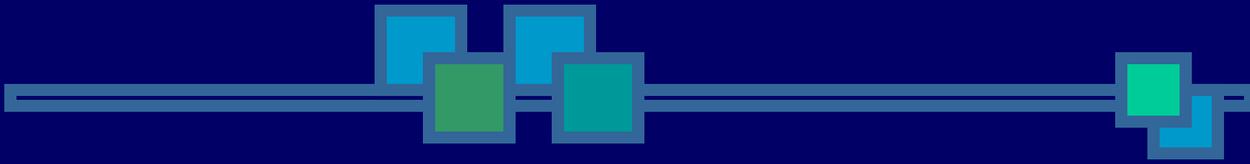

Solution Outline

- **Detection.** Workflows are dynamically adapted when their wQoS metrics are not satisfactory.
- **Change Analysis.** Adaptation alternatives are generated based on adaptation patterns.
- **Change Introduction.** Adaptation is made to currently running workflows through the use of a dynamic change layer to guarantee consistency of workflows after changes.

Workflow Adaptation

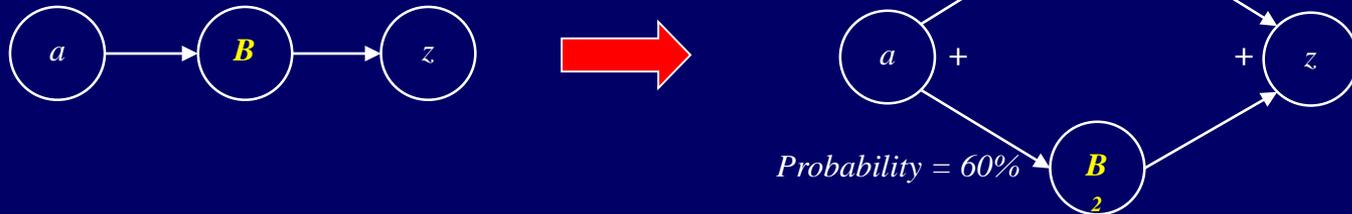

- Dynamically and automatically change a workflow to meet wQoS requirements
 - Non-structural Adaptation
 - Replace a task with an alternative task with attributes that will permit a workflow to exhibit satisfactory wQoS
 - Structural Adaptation
 - Load distribution pattern
 - Decrease **Time**, Increase **Cost**
 - Redundant pattern
 - Increase **Fidelity**, Increase **Cost**
 - More patterns ...

Examples of Structural changes (1)

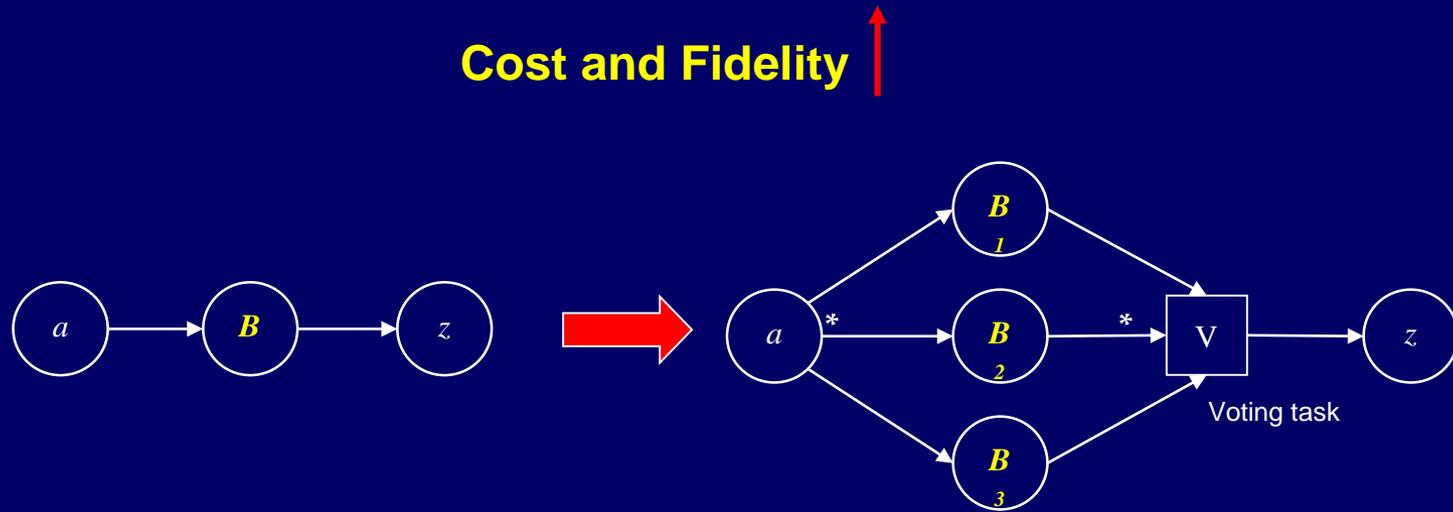

- Load distribution pattern

Cost and Speed ↑

Examples of Structural changes (2)

- Redundancy pattern

Putting all together
